Dark matter or modified gravity: case study #1

W. Herschel

Discovered Uranus 1781

◆□ > ◆□ > ◆豆 > ◆豆 > ̄豆 = のへで

inus	Mercury	Dark matter	Mergers
00	000	000000000	0000000000000000

Suggested causes of poor fit:

Urar

- Unseen matter: unseen planet perturbing Uranus
- Modified gravity: inverse-square law may fail at large distances

Uranus	Mercury	Dark matter	Mergers
0000	000	000000000	000000000000000

Suggested causes of poor fit:

- **Auxiliary assumptions** planet perturbing Uranus
- Modified gravity: inverse-square law may fail at large distances

Uranus	Mercury	Dark matter	Mergers
0000	000	000000000	000000000000

Suggested causes of poor fit:

- **Auxiliary assumptions** planet perturbing Uranus
- Unifying theory inverse-square law may fail at large distances

Uranus	Mercury	Dark matter	Mergers
0000	000	000000000	000000000000

Suggested causes of poor fit:

U

- **Auxiliary assumptions** planet perturbing Uranus
- Unifying theory inverse-square law may fail at large distances

Another option: reject discrepant data

Uranus 00●0

Mercury 000 Dark matter 0000000000 Mergers 000000000000

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

Are these options equally likely?

Consider:

inverse-square law explains an enormous array of other data

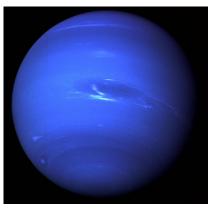

- clues from residual pattern
- simplicity of hypotheses (Occam's razor): physics may be the *only* class your students are exposed to this!

Mercury 000 Dark matter 0000000000 Mergers 000000000000

Resolution: unseen mass

Urbain Le Verrier predicted position and mass of unseen planet in 1846—it was discovered after *one hour* of searching near predicted position.

Case study #2: Mercury precesses too much

- "Normal" precession: 0.15°/century
- "Anomalous" precession: 0.012°/century

Mercury 000 Dark matter

Mergers 000000000000

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

Hypotheses

- Unseen matter: unseen planet ("Vulcan") orbiting near Sun
- **Modified gravity:** steeper than inverse-square? Tinker with speed?

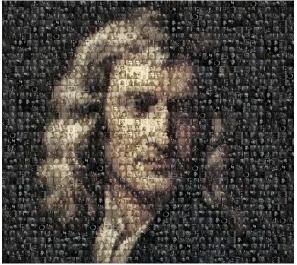

Which seems more likely?

Mercury 00 Dark matter

Mergers 000000000000

Surprise resolution

By 1915 general relativity explained the anomalous precession.

Dark matter or modified gravity?

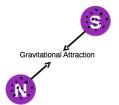

- dark matter is (can be?) an extravagant hypothesis
- but modified gravity struggles to fit so many different environments, e.g. cluster centers vs galaxy outskirts
- \implies dark matter overwhelmingly favored

Can we prove DM more directly by isolating it from normal matter?

gas (from X-rays); mass (from grav. lensing)

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

So what is dark matter? Not protons or neutrons

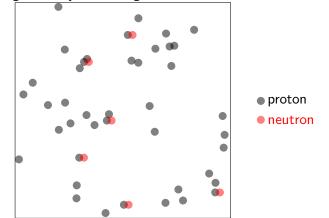

Big Bang nucleosynthesis argument:

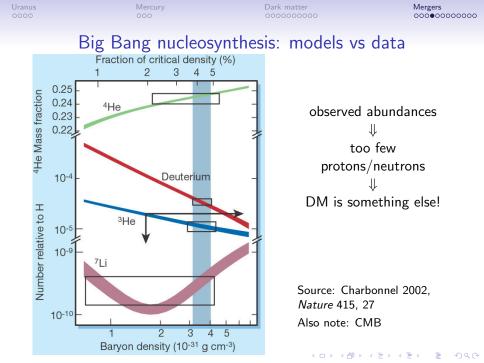

▲ロト ▲帰 ト ▲ ヨ ト ▲ ヨ ト ・ ヨ ・ の Q ()

So what is dark matter? Not protons or neutrons

Big Bang nucleosynthesis argument:

more protons/neutrons \implies less leftover deuterium and more ${}^{4}\text{He}$

Mercury 000 Dark matter 0000000000 Mergers 000000000000

So what *is* dark matter?

We know what it's not:

- not made of protons or neutrons
- does not interact with light
- \implies new particle or particles w/these properties:
 - stable (ish)
 - "cold" (nonrelativistic)
 - collective density $\sim 2 \times 10^{-27} \ \text{kg}/\text{m}^3$
 - does not interact with SM particles (except perhaps weakly)

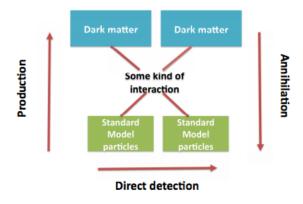

Lots of models to test: WIMPs, axions, hidden-sector models....

The drag force awakens

Self-interacting dark matter (SIDM) would transfer momentum in a collision:

Offset in Bullet is consistent with zero $\implies \sigma_{SIDM} \lesssim 2 \text{ barn/GeV}$ (Randall+08)

Mergers

Wait, 2 *barns* per GeV??

- $\sim 10^{20}$ times larger than upper limits on DM interacting with normal matter
- Incredibly, we don't yet know whether DM particles interact with each other at this level
- Some "hidden sector" particle models predict this, and some galaxy data suggest it
- Only astrophysics can constrain these models!

Can we use clusters as natural colliders to learn more about the DM particle?

▲□▶ ▲□▶ ▲□▶ ▲□▶ □ のQ@

Merging clusters can probe the type of interaction

(1) Frequent interactions w/small momentum transfer—long range force like E&M

(2) infrequent interactions with large momentum transfer—like hard sphere scattering

Merging clusters can probe the type of interaction

(1) Frequent interactions w/small momentum transfer—long range force like E&M

(2) infrequent interactions with large momentum transfer—like hard sphere scattering

(3) no interaction

- the Bullet cluster was the first picture of dark matter without its usual camouflage
- nature provides many more!
- these "Large Dark Matter Colliders" will test particle models robustly

Astronomy and physics work together beautifully to reveal unseen aspects of nature.
