

Mean Field Theory for d=1 Hubbard Model: AntiFerromagnetism

R. T. Scalettar
(Dated: February 9, 2017)

Following up on the preceding note, here I show some results for MFT of the one-dimensional Hubbard model allowing for antiferromagnetism.

I. THE CODE

```

implicit none
integer i,N,Ntot,istag
real*8 t,U,tpin,k,ek,mstag
real*8 rho,Umstag,Urho
real*8 eaf,eaftot,lambdaminus

c      INPUTS

write (6,*) 'N,Ntot,t,U'
read (5,*) N,Ntot,t,U
write (36,*) Ntot/2+1

tpin=8.d0*datan(1.d0)/dfloat(N)
rho=dfloat(Ntot)/dfloat(N)
Urho=U*rho/2.d0

do 1000 istag=0,Ntot,2

mstag=dfloat(istag)/dfloat(N)
Umstag=U*mstag/2.d0

eaftot=0.d0
do 200 i=-Ntot/4+1,Ntot/4
    k=tpin*dfloat(i)
    ek = -2.d0*t*dcos(k)
    lambdaminus=-dsqrt(ek*ek
1      +Umstag*Umstag)
    lambdaminus=lambdaminus+Urho
    eaftot=eaftot+lambdaminus
200  continue
    eaftot=2.d0*eaftot/dfloat(N)
1      -U*(rho*rho-mstag*mstag)/4.d0

write (36,990) istag,eaftot
990  format(i6,f16.6)

1000  continue

end

```

II. RESULTS FOR $\rho = \frac{1}{2}$

Here are results for one quarter filling, that is, a density $\rho = \rho_{\uparrow} + \rho_{\downarrow} = \frac{1}{2}$ electrons per site. (This is one quarter of the maximal density of two electrons per site.) The

FIG. 1: Energy versus staggered magnetization of $d = 1$ Hubbard model at $U/t = 2$ and $\rho = \frac{1}{2}$ (128 electrons on an $N = 256$ site lattice).

staggered magnetization m_s is defined such that the up and down spin densities are $\rho_{\uparrow} = \rho + (-1)^i m_s$ and $\rho_{\downarrow} = \rho - (-1)^i m_s$.

For $U = 2$ the paramagnetic solution $m_s=0$ has lowest energy. We know too from the preceding note that $m = 0$ is the lowest of the ferromagnetic energies. Notice as a check on the codes that one can compare Figure 1 here with the preceding Figure 1 and see that $E(m_s = 0) = E(m = 0)$.

FIG. 2: Energy versus staggered magnetization of $d = 1$ Hubbard model at $U/t = 4$ and $\rho = \frac{1}{2}$ (128 electrons on an $N = 256$ site lattice).

FIG. 3: Energy versus staggered magnetization of $d = 1$ Hubbard model at $U/t = 8$ and $\rho = \frac{1}{2}$ (128 electrons on an $N = 256$ site lattice).

As before, we now start cranking up U . Figures 2 and 3 show the energy for $U = 4$ and $U = 8$ respectively. We see at $U = 8$ that a nonzero m_s is better than zero m_s . However, the state is not actually antiferromagnetic because (Figure 4) the ferromagnetic energy is yet lower. (Again, check the fact that $E(m_s = 0) = E(m = 0)$. Really I should plot the ferromagnetic and antiferromagnetic data, Figures 3 and 4, on the same graph to make comparisons nicer.)

FIG. 4: Energy versus magnetization of $d = 1$ Hubbard model at $U/t = 8$ and $\rho = \frac{1}{2}$ (128 electrons on an $N = 256$ site lattice).

III. RESULTS FOR $\rho = 1$

The preceding results suggest that at quarter filling, $\rho = \frac{1}{2}$, the $d = 1$ Hubbard model is more prone to ferromagnetism than antiferromagnetism. Let's look at half-filling, $\rho = 1$, where antiferromagnetism tends to be most stable. Sure enough, Figures 5 and 6 show the antiferro-

FIG. 5: Energy versus staggered magnetization of $d = 1$ Hubbard model at $U/t = 4$ and $\rho = 1$ (256 electrons on an $N = 256$ site lattice).

FIG. 6: Energy versus magnetization of $d = 1$ Hubbard model at $U/t = 4$ and $\rho = 1$ (256 electrons on an $N = 256$ site lattice).

magnetism is optimal (for $U = 4$). In fact, here, the best m_s is the biggest it can be.

IV. PHASE BOUNDARY

Our ultimate objective could be to analyze a bunch of energy curves, both ferro- and antiferromagnetic, for
 $t=1$ $U=2,4,8,12,16$ $N=256$

FIG. 7: Staggered magnetization m_s which minimizes the energy, as a function of density ρ for the $d = 1$ Hubbard model on a $N = 256$ site lattice. Curves are (left to right) $U = 16, 12, 8, 4, 2$.

different densities ρ and couplings U and figure out the whole phase diagram in the $\rho-U$ plane. As a first step in this direction, Figure 7 shows the value of the staggered magnetization which minimizes the energy, as a function of density for different values of U . For small $U = 2$, the energy is minimized in the paramagnetic phase $m_s = 0$ until close to half filling ($\rho = 1$). As U increases, so does the regime of antiferromagnetism. For $U = 16$ the optimal staggered magnetization becomes nonzero around $\rho = 0.24$. So looking at the five points where m_s becomes nonzero begins to give us a sense of the antiferromagnetic phase boundary. We have to do similar analysis for the ferromagnetic case (and compare energies) to complete the picture.
